Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

Read more about Early Journal Content at http://about.jstor.org/participate-jstor/individuals/early-journal-content.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.
pelled into the more posterior parts of the tubular prolongations, and into the oval bodies in which these terminate. Mr. Bergin had pointed out to Dr. Allman the existence of muscular fibres in the walls of the oval dilatations. The contraction, therefore, of these muscles, will cause the contained fluid to impinge upon the inverted extremity of the proboscis, which will thus be forced outwards, and the proboscis injected with the fluid. The source of this fluid would appear to be in the oval bodies themselves, whose structure is, in all probability, glandular, and which, besides possessing a contractile power, by which the contents of their cavities are expelled, would seem also to be the secretors of the fluid which plays so important a part in the protrusion of the proboscides.

The Chair having been taken pro tem. by the Rev. H. Lloyd, D. D., Vice-President,

The President read a paper on a new Species of Imaginary Quantities, connected with a theory of Quaternions.

It is known to all students of algebra that an imaginary equation of the form \( i^2 = -1 \) has been employed so as to conduct to very varied and important results. Sir Wm. Hamilton proposes to consider some of the consequences which result from the following system of imaginary equations, or equations between a system of three different imaginary quantities:

\[
\begin{align*}
i^2 &= j^2 = k^2 = -1; \\
j &= k, & jk &= i, & ki &= j; \\
jk &= -k, & kj &= i, & ik &= -j;
\end{align*}
\]

no linear relation between \( i, j, k \) being supposed to exist, so that the equation

\[
q = q',
\]

in which

\[
q = w + ix + jy + kz, \\
q' = w' + ix' + jy' + kz',
\]
and \(w, x, y, z, w', x', y', z'\) are real, is equivalent to the four separate equations,

\[
w = w', \quad x = x', \quad y = y', \quad z = z'.
\]

Sir W. Hamilton calls an expression of the form \(q\) a quaternion; and the four real quantities \(w, x, y, z\) he calls the constituents thereof. Quaternions are added or subtracted by adding or subtracting their constituents, so that

\[
q + q' = w + w' + i(x + x') + j(y + y') + k(z + z').
\]

Their multiplication is, in virtue of the definitions (A) (B) (C), effected by the formulæ

\[
\begin{align*}
q q' &= q'' = w'' + i x'' + j y'' + k z'', \\
w'' &= w w' - x x' - y y' - z z', \\
x'' &= w x' + x w' + y z' - z y', \\
y'' &= w y' + y w' + z x' - x y', \\
z'' &= w z' + z w' + x y' - y x',
\end{align*}
\]

which give

\[
w'^2 + x'^2 + y'^2 + z'^2 = (w^2 + x^2 + y^2 + z^2) (w'^2 + x'^2 + y'^2 + z'^2),
\]

and therefore

\[
\mu'' = \mu \mu',
\]

if we call the positive quantity

\[
\mu = \sqrt{w^2 + x^2 + y^2 + z^2},
\]

the modulus of the quaternion \(q\). The modulus of the product of any two quaternions is therefore equal to the product of the moduli. Let

\[
\begin{align*}
w &= \mu \cos \theta, \\
x &= \mu \sin \theta \cos \phi, \\
y &= \mu \sin \theta \sin \phi \cos \psi, \\
z &= \mu \sin \theta \sin \phi \sin \psi;
\end{align*}
\]

then, because the equations (D) give

\[
\begin{align*}
w' w'' + x' x'' + y' y'' + z' z'' &= w (w'^2 + x'^2 + y'^2 + z'^2), \\
w w'' + x x'' + y y'' + z z'' &= w' (w^2 + x^2 + y^2 + z^2),
\end{align*}
\]
we have
\[
\begin{align*}
\cos \theta'' &= \cos \theta \cos \theta' - \sin \theta \sin \theta' (\cos \phi \cos \phi' + \sin \phi \sin \phi' \cos (\psi - \psi')), \\
\cos \theta &= \cos \theta' \cos \theta'' + \sin \theta' \sin \theta'' (\cos \phi' \cos \phi'' + \sin \phi' \sin \phi'' \cos (\psi' - \psi'')), \\
\cos \theta' &= \cos \theta'' \cos \theta + \sin \theta'' \sin \theta (\cos \phi' \cos \phi' + \sin \phi' \sin \phi' \cos (\psi' - \psi')).
\end{align*}
\]

(6)

Consider \(x, y, z\) as the rectangular coordinates of a point of space, and let \(R\) be the point where the radius vector of \(x, y, z\) (prolonged if necessary) intersects the spheric surface described about the origin with a radius equal to unity; call \(R\) the representative point of the quaternion \(Q\), and let the polar coordinates \(\phi\) and \(\psi\), which determine \(R\) upon the sphere, be called the co-latitude and the longitude of the representative point \(R\), or of the quaternion \(Q\) itself; let also the other angle \(\theta\) be called the amplitude of the quaternion; so that a quaternion is completely determined by its modulus, amplitude, co-latitude, and longitude. Construct the representative points \(R'\) and \(R''\), of the other factor \(Q'\), and of the product \(Q''\); and complete the spherical triangle \(RR'R''\), by drawing the arcs \(RR', RR'', RR''\). Then, the equations (6) become

\[
\begin{align*}
\cos \theta'' &= \cos \theta \cos \theta' - \sin \theta \sin \theta' \cos RR', \\
\cos \theta &= \cos \theta' \cos \theta'' + \sin \theta' \sin \theta'' \cos RR'', \\
\cos \theta' &= \cos \theta'' \cos \theta + \sin \theta'' \sin \theta \cos RR',
\end{align*}
\]

and consequently shew that the angles of the triangle \(RR'R''\) are

\[
R = \theta, \quad R' = \theta', \quad R'' = \pi - \theta'';
\]

(7)

these angles are therefore respectively equal to the amplitudes of the factors, and the supplement (to two right angles) of the amplitude of the product. The equations (7) show, further, that the product-point \(R''\) is to the right or left of the multiplicand-point \(R'\), with respect to the multiplier-point \(R\), according as the semiaxis of \(+ z\) (or its intersection with the spheric surface) is to the right or left of the semiaxis of \(+ y\), with respect to the semiaxis of \(+ x\): that is, according as the positive direction of rotation in longitude is towards the right or left. A change in the
order of the two quaternion-factors would throw the product-point \( r'' \) from the right to the left, or from the left to the right of \( rr' \).

It results from these principles, that if \( rr' r'' \) be any spherical triangle; if, also, \( a \beta \gamma \) be the rectangular coordinates of \( r \), \( a' \beta' \gamma' \) those of \( r' \), and \( a'' \beta'' \gamma'' \) of \( r'' \), the centre of the sphere being origin, and the radius being unity; and if the rotation round \( +x \) from \(+y\) to \(+z\) be of the same (right-handed or left-handed) character as that round \( r \) from \( r' \) to \( r'' \); then the following formula of multiplication, according to the rules of quaternions, will hold good:

\[
\{ \cos r + (ia + j\beta + k\gamma) \sin r \} \{ \cos r' + (ia' + j\beta' + k\gamma') \sin r' \} = - \cos r'' + (ia'' + j\beta'' + k\gamma'') \sin r''.
\]

Developing and decomposing this imaginary or symbolic formula (i), we find that it is equivalent to the system of the four following real equations, or equations between real quantities:

\[
\begin{align*}
- \cos r'' & = \cos r \cos r' - (a' a' + \beta' \beta' + \gamma' \gamma') \sin r \sin r'; \\
a'' \sin r'' & = a \sin r \cos r' + a' \sin r' \cos r + (\beta' \beta' - \gamma' \gamma') \sin r \sin r'; \\
\beta'' \sin r'' & = \beta \sin r \cos r' + \beta' \sin r' \cos r + (\gamma' \gamma' - a' a') \sin r \sin r'; \\
\gamma'' \sin r'' & = \gamma \sin r \cos r' + \gamma' \sin r' \cos r + (a' a' - \beta' \beta') \sin r \sin r'.
\end{align*}
\]

Of these equations (k), the first is only an expression of the well-known theorem, already employed in these remarks, which serves to connect a side of any spherical triangle with the three angles thereof. The three other equations (k) are an expression of another theorem (which possibly is new), namely, that a force \( = \sin r'' \), directed from the centre of the sphere to the point \( r'' \), is statically equivalent to the system of three other forces, one directed to \( r \), and equal to \( \sin r \cos r' \), another directed to \( r' \), and equal to \( \sin r' \cos r \), and the third equal to \( \sin r \sin r' \cos r' \), and directed towards that pole of the arc \( rr' \), which lies at the same side of this arc as \( r'' \). It is not difficult to prove this theorem otherwise; but it may be regarded as interesting to see that the four equations (k) are included so simply in the one formula.
of multiplication of quaternions, and are obtained so easily by developing and decomposing that formula, according to the fundamental definitions (a) (b) (c). A new sort of algorithm, or calculus, for spherical trigonometry, appears to be thus given, or indicated. And by supposing the three corners of the spherical triangle $RR'R''$ to tend indefinitely to close up in that one point which is the intersection of the spheric surface with the positive semiaxis of $x$, each coordinate $a$ will tend to become $= 1$, and each $\beta$ and $\gamma$ to vanish, while the sum of the three angles will tend to become $= \pi$; so that the following well known and important equation in the usual calculus of imaginaries, as connected with plane trigonometry, namely,

$$(\cos R + i \sin R)(\cos R' + i \sin R') = \cos (R + R') + i \sin (R + R'),$$

(in which $i^2 = -1$), is found to result, as a limiting case, from the more general formula (i).

In the ordinary theory there are only two different square roots of negative unity ($+ i$ and $- i$), and they differ only in their signs. In the present theory, in order that a quaternion, $w + i x + j y + k z$, should have its square $= -1$, it is necessary and sufficient that we should have

$$w = 0, \quad x^2 + y^2 + z^2 = +1;$$

we are conducted, therefore, to the extended expression,

$$\sqrt{-1} = i \cos \phi + j \sin \phi \cos \psi + k \sin \phi \sin \psi, \quad (1)$$

which may be called an imaginary unit, because its modulus is $= 1$, and its square is negative unity. To distinguish one such imaginary unit from another, we may adopt the notation,

$$i_a = ia + j\beta + k\gamma,$$

which gives $i_a^2 = -1, \quad (1')$

$\alpha$ being still that point upon the spheric surface which has $a, \beta, \gamma$ (or $\cos \phi, \sin \phi \cos \psi, \sin \phi \sin \psi$) for its rectangular coordinates; and then the formula of multiplication (i) be-
comes, for any spherical triangle, in which the rotation round \( R \), from \( R' \) to \( R'' \), is positive,

\[
(cos \, R + i_n \, \sin \, R) \, (cos \, R' + i_{n'} \, \sin \, R') = - cos \, R'' + i_{n''} \, \sin \, R''. \quad (i')
\]

If \( R'' \) be the \textit{positive pole} of the arc \( RR' \), or the pole to which the least rotation from \( R' \) round \( R \) is positive, then the product of the two imaginary units in the first member of this formula (which may be any two such units), is the following:

\[
i_n \, i_{n'} = - \cos \, RR' + i_{n'} \, \sin \, RR'. \quad (M)
\]

we have also, for the product of the same two factors, taken in the opposite order, the expression

\[
i_{n'} \, i_n = - \cos \, RR' - i_{n'} \, \sin \, RR', \quad (N)
\]

which differs only in the sign of the imaginary part; and the product of these two products is unity, because, in general,

\[
(w + ix + jy + k\,z) \, (w - ix - jy - k\,z) = w^2 + x^2 + y^2 + z^2; \quad (o)
\]

we have, therefore,

\[
i_n \, i_{n'} \cdot i_{n'} \, i_n = 1, \quad \text{(P)}
\]

and the products \( i_n \, i_{n'} \) and \( i_{n'} \, i_n \) may be said to be \textit{reciprocals} of each other.

In general, in virtue of the fundamental equations of definition, \((\lambda), (\mu), (c)\), although the \textit{distributive} character of the multiplication of ordinary algebraic quantities (real or imaginary) extends to the operation of the same name in the theory of quaternions, so that

\[
q \, (q' + q'') = q \, q' + q \, q'', \quad \text{&c.,}
\]

yet the \textit{commutative} character is lost, and we cannot generally write for the new as for the old imaginaries,

\[
q \, q' = q' \, q,
\]

since we have, for example, \( j \, i = - \, i \, j \). However, in virtue of the same definitions, it will be found that another important property of the old multiplication is preserved, or extended
to the new, namely, that which may be called the *associative* character of the operation, and which may have for its type the formula

\[ q \cdot q' q'' = q q' q'' \;
\]

thus we have, generally,

\[ q \cdot q' q'' = q q' q'' \quad (q)
\]

\[ q \cdot q'' q''' = q q' q'' \quad (q')
\]

and so on for any number of factors; the notation \( q q' q'' \) being employed to express that one determined quaternion, which, in virtue of the theorem \((q)\), is obtained, whether we first multiply \( q'' \) as a multiplicand by \( q' \) as a multiplier, and then multiply the product \( q' q'' \) as a multiplicand by \( q \) as a multiplier; or multiply first \( q' \) by \( q \) and then \( q'' \) by \( q q' \).

With the help of this principle, we might easily prove the equation \((v)\), by observing that its first member \( = i_n i_n' i_n = -i_n^2 = 1 \).

In the same manner it is seen at once that

\[ i_n i_n' \cdots i_n^r i_n^s \cdots i_n^{(n-1)} i_n = (-1)^n \quad (v')\]

whatever \( n \) points upon the spheric surface may be denoted by \( r, r', r'', r''' \ldots r^{(n-1)} \); and by combining this principle with that expressed by \((m)\), it is not difficult to prove that for any spherical polygon, \( r r' \ldots r^{(n-1)} \), the following formula holds good:

\[ (\cos r + i_n \sin r) (\cos r' + i_n' \sin r') (\cos r'' + i_{n'} \sin r'') \cdots (\cos r^{(n-1)} + i_{n^{(n-1)}} \sin r^{(n-1)}) = (-1)^n \quad (r)\]

which includes the theorem \((v')\) for the case of a spherical triangle, and in which the arrangement of the \( n \) points may be supposed, for simplicity, to be such that the rotations round \( r \) from \( r' \) to \( r'' \), round \( r' \) from \( r'' \) to \( r''' \), and so on, are all positive, and each less than two right angles, though it is easy to interpret the expression so as to include also the cases where any or all of these conditions are violated.

When the polygon becomes infinitely small, and therefore
plane, the imaginary units become all equal to each other, and may be denoted by the common symbol $i$; and the formula (r) agrees then with the known relation, that
\[
\pi - \mathbf{r} + \pi - \mathbf{r}' + \pi - \mathbf{r}'' + \ldots + \pi - \mathbf{r}^{(n-1)} = 2\pi.
\]
Again, let $\mathbf{r}, \mathbf{r}', \mathbf{r}''$ be, respectively, the representative points of any three quaternions $Q, Q', Q''$, and let $\mathbf{r}_\nu, \mathbf{r}_\mu, \mathbf{r}_\nu$ be the representative points of the three other quaternions, $Q Q', Q Q'', Q Q' Q''$, derived by multiplication from the former; then the algebraical principle expressed by the formula (q) may be geometrically enunciated by saying that the two points $\mathbf{r}_\nu$ and $\mathbf{r}_\mu$ are the foci of a spherical conic which touches the four sides of the spherical quadrilateral $\mathbf{r} R' R'' R''$; and analogous theorems respecting spherical pentagons and other polygons may be deduced, by constructing similarly the formulae (q'), &c.

In general, a quaternion $Q$, like an ordinary imaginary quantity, may be put under the form,
\[
Q = \mu \left( \cos \theta + (-1)^{\frac{1}{2}} \sin \theta \right) = w + (-1)^{\frac{1}{2}} r,
\]
provided that we assign to $(-1)^{\frac{1}{2}}$, or $\sqrt{-1}$, the extended meaning (l), which involves two arbitrary angles; and the same general quaternion $Q$ may be considered as a root of a quadratic equation, with real coefficients, namely,
\[
Q^2 - 2wQ + \mu^2 = 0,
\]
which easily conduct to the following expression for a quotient, or formula for the division of quaternions,
\[
Q^{-1} Q'' = \frac{Q''}{Q} = \frac{Q''}{\mu^2} Q^\nu,
\]
if we define $Q^{-1} Q''$ or $\frac{Q''}{Q}$ to mean that quaternion $Q'$ which gives the product $Q''$, when it is multiplied as a multiplicand by $Q$ as a multiplier. The same general formula (s'') of division may easily be deduced from the equation (o), by writing that equation as follows,
or it may be obtained from the four general equations of multiplication \(s\), by treating the four constituents of the multiplicand, namely, \(w', x', y', z'\), as the four sought quantities, while \(w, x, y, z\), and \(w'', x'', y'', z''\), are given; or from a construction of spherical trigonometry, on principles already laid down.

The general expression \(s\) for a quaternion may be raised to any power with a real exponent \(q\), in the same manner as an ordinary imaginary expression, by treating the square root of \(-1\) which it involves as an imaginary unit \(i_a\) having (in general) a fixed direction; raising the modulus \(\mu\) to the proposed real power; and multiplying the amplitude \(\theta\), increased or diminished by any whole number of circumferences, by the exponent \(q\): thus,

\[
(\mu (\cos \theta + i_a \sin \theta))^q = \mu^q (\cos q(\theta + 2n\pi) + i_a \sin q(\theta + 2n\pi)),
\]

if \(q\) be real, and if \(n\) be any whole number. For example, a quaternion has in general two, and only two, different square roots, and they differ only in their signs, being both included in the formula,

\[
(\mu (\cos \theta + i_a \sin \theta))^q = \mu^q \left( \cos \left( \frac{\theta}{2} + n\pi \right) + i_a \sin \left( \frac{\theta}{2} + n\pi \right) \right),
\]

in which it is useless to assign to \(n\) any other values than 0 and 1; although, in the particular case where the original quaternion reduces itself to a real and negative quantity, so that \(\theta = \pi\), this formula \(t'\) becomes

\[
(-\mu)^q = \pm \mu^q i_a, \text{ or simply } (-\mu)^q = \mu^q i_a,
\]

the direction of \(i_a\) remaining here entirely undetermined; a result agreeing with the expression \(l\) or \(l'\) for \(\sqrt{-1}\). In like manner the quaternions, which are cube roots of unity, are included in the expression,

\[
1^q = \cos \frac{2n\pi}{3} + i_a \sin \frac{2n\pi}{3}, \quad (t'')
\]
\(i_a\) denoting here again an imaginary unit, with a direction altogether arbitrary.

If we make, for abridgment,

\[
f'(q) = 1 + \frac{q}{1} + \frac{q^2}{1 \cdot 2} + \frac{q^3}{1 \cdot 2 \cdot 3} + \&c.,
\]

the series here indicated will be always convergent, whatever quaternion \(q\) may be; and we can always separate its real and imaginary parts by the formula,

\[
f'(w + i_a r) = f(w) (\cos r + i_a \sin r);
\]

which gives, reciprocally, for the inverse function \(f^{-1}\), the expression

\[
f^{-1}(\mu (\cos \theta + i_a \sin \theta)) = \log \mu + i_a (\theta + 2n\pi),
\]

\(w\) being any whole number, and \(\log \mu\) being the natural, or Napierian, logarithm of \(\mu\), or, in other words, that real quantity, positive or negative, of which the function \(f\) is equal to the given real and positive modulus \(\mu\). And although the ordinary property of exponential functions, namely,

\[
f'(q) \cdot f'(q') = f'(q + q'),
\]

does not in general hold good, in the present theory, unless the two quaternions \(q\) and \(q'\) be codirectional, yet we may raise the function \(f\) to any real power by the formula

\[
(f'(w + i_a r))^q = f'(w + i_a r + 2n\pi),
\]

which it is natural to extend, by definition, to the case where the exponent \(q\) becomes itself a quaternion. The general equation,

\[
q^q = q',
\]

when put under the form

\[
(f'(w + i_a r))^q = f'(w + i_a r'),
\]

will then give

\[
q = \frac{\{w + i_a (r' + 2n' \pi)\} \{w - i_a (r + 2n \pi)\}}{w^2 + (r + 2n \pi)^2};
\]

and thus the general expression for a quaternion \(q\), which is
one of the logarithms of a given quaternion \( q' \), to a given base
\( q \), is found to involve two independent whole numbers \( n \) and
\( n' \), as in the theories of Graves and Ohm, respecting the ge-
neral logarithms of ordinary imaginary quantities to ordinary
imaginary bases.

For other developments and applications of the new
tory, it is necessary to refer to the original paper from
which this abstract is taken, and which will probably appear
in the twenty-first volume of the Transactions of the Aca-
demy.

November 30. (Stated Meeting.)

REV. H. LLOYD, D. D., Vice-President, in the Chair.

The Rev. Dr. Todd, V.P., presented to the Academy, in
his name and that of Mr. O'Donovan, a volume containing
tracings made from Irish MSS. preserved in the College of
St. Isidore at Rome, by the Rev. Dr. Lyons, who had sent
them from Rome, some to Mr. O'Donovan, and the re-
mainder to Dr. Todd.

The thanks of the Academy were voted to Mr. O'Donovan
and also to the Rev. Dr. Lyons, for the important service
he has rendered to Irish literature, by making known the
existence of these MSS.

The Rev. Dr. Todd made some remarks on the progress
of the Catalogue, made by Mr. Eugene Curry, of the Irish
MSS. in the Library of the Academy.

The miscellaneous character of the MSS., almost every
volume of them containing tracts or poems, wholly uncon-
ected with each other, rendered it impossible to attempt
any previous classification. Mr. Curry, therefore, took the
MSS. in the order in which they stood on the shelves of the
Library, hoping that all the important objects of a classifica-
